Abstract of DE19751226

The syringe involved is particularly for a substance which for medical purposes is subjected to a lyophilising process. It is formed by a syringe cylinder (1) in which is arranged a plug (2), at one end of which is a canula extension or closure part and at its other end a finger location with a piston rod can be applied. A filling container (3) can be applied with a connecting part (8) to one of the two ends of the syringe cylinder (1) and sealed against it. The filling container in the applied state to the syringe cylinder has a filling aperture (9) for the substance at its upper end. The connecting part of the filling container is formed by a cylinder casing (10), which positively engages around the outside of the syringe cylinder.
